Perspective

The Potential Role of Neutrophils in Promoting the Metastatic Phenotype of Tumors Releasing Interleukin-8

Vol. 10, 4895–4900, August 1, 2004

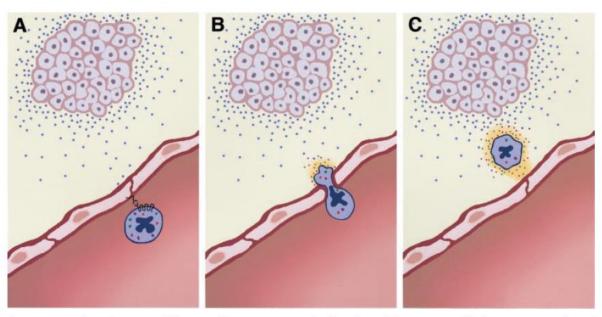

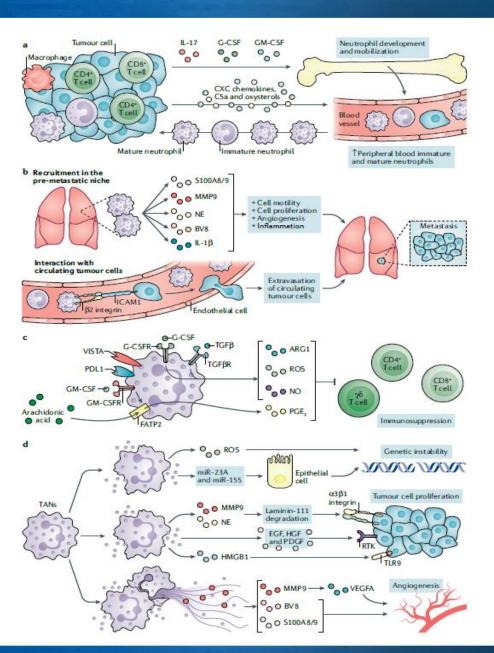

Fig. 1 A schematic representation of a neutrophil responding to IL-8 ectopically released by a tumor with the consequent invasion and remodeling of the ECM. A, the neutrophil (represented as a blue cell) binds to the IL-8 molecules (blue dots) that were released by the tumor and tethered to the vascular endothelial cells. This interaction contributes to the activation of the neutrophil. B, the emigration of an "activated" neutrophil from the vascular compartment. During this process, the neutrophil gains access to the ECM (light yellow area) and releases vesicles of enzymes (red, green, and purple dots) that initiate ECM remodeling (the darker yellow). C, the neutrophil, responding to the IL-8 concentration gradient, migrates toward the tumor. Remodeling the ECM during this process thereby establishes an environment more favorable to the progression and metastasis of the tumor cells.

Figure 2 Forest plot of the association between the neutrophil to lymphocyte ratio and overall survival in patients with lung cancer receiving immunotherapy.

Jin J, Yang L, Liu D et al. Association of the NLR and clinical outcomes in patients with lung cancer receiving immunotherapy: a meta-analysis. BMJ Open. 2020;10(6):e035031.

Study objective:

- Analysis of the correlation between pre-treatment neutrophil-to-lymphocyte ratio (NLR), Disease Control Rate (DCR) and Duration Of Response (DOR) in advanced NSCLC treated with immunotherapy.
- Assess a global correlation and a specific one in the CT-IT and IT group.
- Stratify the NLR with prognostic/predictive factors (age, histology, ECOG-PS, steroid and antibiotic use, smoking status, PD-L1...).

Secondary objectives:

- Analysis between NLR, Objective Response Rate (ORR), Progression Free Survival (PFS) and Overall Survival (OS).
- Construct a ROC defining cut-off point to refine the analysis.

Patient selection. Retrospective analysis.

- Patients diagnosed with NSCLC in a metastatic stage or who have relapsed after a curative treatment.

- First line treatment with inmmunotherapy or chemoimmunotherapy between January 2020 and January 2023.

- **Blood cell counts** used to measure NLR were performed whithin a **month prior to the start of the treatment**.

- A minimum of 4 months was required in order to assess response.

Baseline characteristics

Age: range from 31 to 89 yo. Median 64.5 yo.

Sex: 55.5% men. 44.4% women.

Smoking status: 93.3% smokers (59.5% active and 40.5%

former smokers).

Median pack-years: 48.

ECOG-PS: 74.4% were PS1.

Histology: adenocarcinoma 67.8%, SCC 20%.

NGS in 75.6% of patients.

Driver mutations: 14.3% KRAS G12C, 5.2% EGFR mut.

Stage IV at diagnosis: 75.6%.

Conclusions

No association between NLR, DCR and DOR was found in a retrospective analysis of our study population with a cut-off point of 5.

In the subgroup analysis, a trend for statistical significance was observed in those patients who are ≥70 yo. and PD-L1 negative.

An univariate analysis was made to carry out the first exploratory analysis. A multivariate analysis will be made in a second stage.

Next step will be performing an analysis of the **correlation between NLR and ORR according RECIST criteria, PFS and OS** including additional factors (PS, smoking status, gender, steroids and antibiotics use).
